# TUPLES, LISTS, MUTABILITY, CLONING

#### TUPLES

an ordered sequence of elements, can mix element types

immutable, cannot change element values remembel

represented with parentheses

$$te = () e^{mpty}$$

$$t = (2, "one", 3)$$

$$t[0] \rightarrow evaluates to 2$$

$$(2, "one", 3) + (5, 6) \rightarrow evaluates to (2, "one", 3, 5, 6)$$

$$t[1:2] \rightarrow slice tuple, evaluates to ("one", )$$

$$t[1:3] \rightarrow slice tuple, evaluates to ("one", 3)$$

$$e^{xtra comma}$$

$$terra comma$$

$$e^{xtra comma}$$

 $t[1] = 4 \rightarrow$  gives error, can't modify object

#### TUPLES

#### conveniently used to swap variable values

used to return more than one value from a function

def quotient\_and\_remainder(x, y): q = x//y r = x%y return (q, r) (quot, rem) = quotient\_and\_remainder(4,5)

#### 6.00.1X LECTURE

#### LISTS

- ordered sequence of information, accessible by index
- a list is denoted by square brackets, []
- a list contains elements
  - usually homogeneous (i.e., all integers)
  - can contain mixed types (not common)
- Iist elements can be changed so a list is mutable

# INDICES AND ORDERING

an element of a list is at a position (aka index) in list, indices start at 0

- Index can be a variable or expression, must evaluate to an int
- i = 2L[i-1]  $\rightarrow$  evaluates to 1 since L[1] = 1 from above

#### CHANGING ELEMENTS

- lists are mutable!
- assigning to an element at an index changes the value
  - L = [2, 1, 3]
  - L[1] = 5

L is now [2, 5, 3], note this is the same object L

#### ITERATING OVER A LIST

- compute the sum of elements of a list
- common pattern

```
total = 0
for i in range(len(L)):
    total += L[i]
print(total)
```

- notice
  - list elements are indexed 0 to len(L) −1
  - range(n) goes from 0 to n-1

#### 6.00.1X LECTURE

# OPERATIONS ON LISTS - ADD

- add elements to end of list with L.append (element)
- mutates the list!

$$L = [2,1,3]$$
  
L.append(5)  $\rightarrow$  L is now [2,1,3,5  
 $\uparrow$  what is  
this dot?

- what is the dot?
  - lists are Python objects, everything in Python is an object
  - objects have data
  - objects have methods and functions
  - access this information by object\_name.do\_something()
  - will learn more about these later

#### **OPERATIONS ON LISTS - ADD**

- to combine lists together use concatenation, + operator
- mutate list with L.extend(some\_list)

- L1 = [2, 1, 3]
- L2 = [4, 5, 6]
- L3 = L1 + L2
- L1.extend([0,6])
- → L3 is [2,1,3,4,5,6]
- → mutated L1 to [2,1,3,0,6]

#### OPERATIONS ON LISTS -REMOVE

- delete element at a specific index with del(L[index])
- remove element at end of list with L.pop(), returns the removed element
- remove a specific element with L.remove (element)
  - looks for the element and removes it
  - if element occurs multiple times, removes first occurrence
  - if element not in list, gives an error

#### CONVERT LISTS TO STRINGS AND BACK

- convert string to list with list(s), returns a list with every character from s an element in L
- can use s.split(), to split a string on a character parameter, splits on spaces if called without a parameter
- use ''.join(L) to turn a list of characters into a string, can give a character in quotes to add char between every element

s = "I <3 cs" → s is a string list(s) → returns ['I', ', '<', '3', ', ', 'c', 's'] s.split('<') → returns ['I ', '3 cs'] L = ['a', 'b', 'c'] → L is a list '.join(L) → returns "abc" '\_'.join(L) → returns "a\_b\_c"

# OTHER LIST OPERATIONS

- sort() and sorted()
- reverse()
- and many more! <u>https://docs.python.org/2/tutorial/datastructures.html</u>

- L = [9, 6, 0, 3]
- sorted(L)
- L.sort()
- L.reverse()

- $\rightarrow$  returns sorted list, does **not mutate** L
- → mutates L=[0,3,6,9]
- → mutates L=[9,6,3,0]

# BRINGING TOGETHER LOOPS, FUNCTIONS, range, and LISTS

- range is a special procedure
  - returns something that behaves like a tuple!
  - doesn't generate the elements at once, rather it generates the first element, and provides an iteration method by which subsequent elements can be generated
- range(5)
  range(2,6)
  range(5,2,-1)
- $\rightarrow$  equivalent to tuple [0, 1, 2, 3, 4]
- range (2, 6)  $\rightarrow$  equivalent to tuple [2, 3, 4, 5]
- range (5, 2, -1)  $\rightarrow$  equivalent to tuple [5, 4, 3]
- when use range in a for loop, what the loop variable iterates over behaves like a list!

```
for var in range(5):
     <expressions>
```

behind the scenes, gets converted to something that will behave like:

```
for var in (0,1,2,3,4):
     <expressions>
```

#### 6.00.1X LECTURE

#### MUTATION, ALIASING, CLONING

Python Tutor is your best friend to help sort this out!

http://www.pythontutor.com/

#### LISTS IN MEMORY

- lists are mutable
- behave differently than immutable types
- is an object in memory
- variable name points to object
- any variable pointing to that object is affected
- key phrase to keep in mind when working with lists is side effects

Justin Drew Bieber

Justin Bieber

JB

#### AN ANALOGY

- attributes of a person
   singer, rich
- he is known by many names
- all nicknames point to the same person
  - add new attribute to one nickname ...

Justin Bieber: singer, rich , troublemaker

• ... all his nicknames refer to old attributes AND all new ones

The Bieb is:singer, rich, troublemakerJBeebs is:singer, rich, troublemakeretc...

#### PRINT IS NOT ==

- if two lists print the same thing, does not mean they are the same structure
- can test by mutating one, and checking

#### ALIASES

- hot is an alias for warm changing one changes the other!
- append() has a side effect

#### CLONING A LIST

• create a new list and copy every element using chill = cool[:]

```
Frames
                                                                   Objects
cool = ['blue', 'green', 'grey']
chill = cool[:]
                                               Global frame
                                                                    list
                                                    cool
                                                                     "blue"
                                                                              "green"
                                                                                       "grey"
chill.append('black')
                                                    chill
print(chill)
print(cool)
                                                                    list
                                                                     0
                                                                     "blue"
                                                                              "green"
                                                                                       "grey"
```

#### SORTING LISTS

- calling sort() mutates the list, returns nothing
- calling sorted() does not mutate list, must assign result to a variable

#### LISTS OF LISTS OF LISTS OF ....

- can have nested lists
- side effects still possible after mutation

```
warm = ['yellow', 'orange']
hot = ['red']
brightcolors = [warm]
brightcolors.append(hot)
```

```
print(brightcolors)
```

```
hot.append('pink')
print(hot)
print(brightcolors)
```

```
print(hot + warm)
print(hot)
```

### MUTATION AND ITERATION

#### avoid mutating a list as you are iterating over it

remove dups(L1, L2)

- L1 is [2,3,4] not [3,4] Why?
  - Python uses an internal counter to keep track of index it is in the loop
  - mutating changes the list length but Python doesn't update the counter
  - loop never sees element 2

if e in L2:

L1.remove(e)

clone list first, note that  $L^{1}_{COPY} = L^{1}_{COPY}$ 

does NOT clone
